Alexander N. Kirdin

## BACKGROUND OF THE INVENTION

### 1. Field of the Invention

The present invention relates to a communications network, and more particularly, to a wireless communications network.

### 2. Background Art

Omni-directional antennas have been implemented in various types of mobile communications devices in a conventional wireless network, for example, a digital mobile telephone network. In addition to voice communications, attempts have been made to provide high speed data communications between various types of apparatus including, for example, desktop computers, laptop computers, servers, peripherals and power management hubs in a wireless network. Compared to voice communications, data communications typically require a large bandwidth, a very low bit error rate, and ability to communicate with multiple devices at different physical locations.

#### DETAILED DESCRIPTION

FIG. 1 shows a partially cutaway perspective view of an embodiment of a direction-agile antenna system for use in a mobile wireless communications network.

In this embodiment, the antenna system includes a

mechanically steered antenna 12 enclosed within a dielectric cover 11. A motor driver 13 is connected to a motor 14 which is capable of rotating the antenna 12 to a desired direction. In an embodiment, the motor 14 is capable of rotating the antenna 12 through 360° in azimuth to scan the antenna beam in a horizontal plane. In a further embodiment, the motor driver 13 is capable of driving the antenna 12 to scan in both azimuth and elevation.

In an embodiment, the antenna 12 is a planar microstrip antenna which comprises a plurality of microstrip antenna elements capable of transmitting and receiving electromagnetic signals in a direction having a positive antenna gain. Other types of directional antennas with positive antenna gains in desired directions may also be implemented in the direction-agile antenna system within the scope of the present invention. For example, parabolic reflector antennas, cassegrain antennas, waveguide slot array antennas and phased array antennas capable of producing directional electromagnetic beam patterns may be implemented in the direction-agile antenna system. Various types of conventional antennas can be designed to produce desired beam patterns in a conventional manner apparent to a person skilled in the art.

FIGS. 2A and 2B show side-sectional views of the direction-agile antenna system with a mechanically steered antenna of FIG. 1 obtained along sectional lines 2a-2a and 2b-2b, respectively.

FIG. 3 shows a block diagram of an embodiment of a controller for selecting the direction of electromagnetic transmission and reception by the antenna in the direction-agile antenna system. The controller 20 is capable of generating a direction-selection signal to steer the electromagnetic signal transmitted by the antenna 12 to a selected direction corresponding to a high gain position, in response to detecting an expected signal transmitted within the wireless communications network. In an embodiment, the controller 20 has a drive signal output 22 connected to a motor 14 in a mechanically steered direction-agile antenna system. Furthermore, the controller 20 has a radio frequency (RF) input 24 and an RF output 26 connected to the antenna 12.

In an embodiment, the controller 20 comprises a transceiver 40 and an antenna control unit 30. The transceiver 40, which is connected to the antenna 12 through the RF input 24 and the RF output 26, is capable of generating an antenna gain signal in response to detecting an expected signal transmitted by

another wireless device within the wireless communications network. The antenna gain signal generated by the transceiver 40 is transmitted to the antenna control unit 30, which generates a direction-selection signal to steer the antenna 12 to a desired direction in response to the antenna gain signal.

In an embodiment, the transceiver 40 comprises a demodulator 41 connected to the RF input 24 to convert the received RF signal to a baseband signal. In an embodiment, the demodulator 41 converts the received RF signal to the baseband signal in multiple stages in a manner apparent to a person skilled in the art. For example, the RF signal may be first converted to an intermediate frequency (IF) signal and then demodulated into a baseband signal. To reduce the effect of noise spectrum in the received RF signal, a low noise amplifier (LNA) 48 is connected between the antenna 12 and the demodulator 41 in an embodiment.

In an embodiment, the transceiver 40 further comprises a baseband processor 42 connected to the demodulator 41 to generate the antenna gain signal which is transmitted to the antenna control unit 30. In an embodiment, the baseband processor 42 is capable of processing data transmitted and received by the direction-agile antenna system in addition to

generating the antenna gain signal for steering the antenna beam to a desired direction to communicate with another wireless device within the wireless network. In this embodiment, the data transmitted and received  
5 by the direction-agile antenna system are transferred between the baseband processor 42 and a computer 46, which is capable of further transferring the data to peripherals through an interface, for example, a universal serial bus (USB) interface.

10 In an embodiment, the transceiver 40 further comprises a modulator 44 connected to the baseband processor 42, which generates baseband signals carrying the data to be transmitted by the direction-agile antenna system to another wireless device within the  
15 wireless network. The modulator 44 modulates the baseband signals generated by the baseband processor 42 to generate RF signals. In an embodiment, the RF signals generated by the modulator 44 are amplified by a power amplifier 43, which is connected between the  
20 modulator 44 and the antenna 12. The demodulation of RF signals into baseband signals and the modulation of baseband signals into RF signals can be performed in a conventional manner apparent to a person skilled in the art.

FIG. 4 shows a block diagram of an embodiment of an antenna control unit which is applicable to a direction-agile antenna system with a mechanically steered antenna. In this embodiment, the antenna control unit 30 comprises a digital signal processor (DSP) 32 which is connected to receive the antenna gain signal from the baseband processor 42 via signal path 36. In an embodiment, the digital signal processor 32 is also connected to flash and random access memory (RAM) 33. In an embodiment, the memory 33 stores application software which embeds the algorithm for generating a direction-selection signal for the antenna. In an embodiment, the digital signal processor 32 generates the direction-selection signal based upon the instant gain of the antenna in the desired direction, the instant angle of the antenna and the parameters of the driving motor.

In an embodiment in which the direction-agile antenna is mechanically steered by a step motor, the antenna control unit 30 further comprises a step motor driver 38 connected between the digital signal processor 32 and the motor 14 for rotating the antenna 12. The motor 14 is capable of rotating the antenna 12 to the selected direction in response to the direction-selection signal received by the step motor driver 38.

In a further embodiment, a DC/DC regulator 31 is connected to the digital signal processor 32 and the motor 14. In an embodiment, a feedback path 37 is provided between the antenna 12 and the digital signal processor 32 to indicate the current angular position of the antenna to the processor 32, thereby allowing the processor 32 to track the movement of the antenna with better accuracy.

FIG. 5 illustrates a mobile wireless network which includes a plurality of mobile wireless devices using direction-agile antennas. In FIG. 5, three laptop computers 51, 52 and 53 are equipped with direction-agile antennas 65, 66 and 67, respectively. One of the wireless communication devices which seeks to initiate a wireless data link is called a master device, whereas another wireless communication device which responds to the request to establish the data link is called a slave device. For example, the mobile wireless communication device 51 may be a master device which seeks to establish a wireless data link with either the wireless communication device 52 or the wireless communication device 53.

The direction-agile antenna 65 of the master device 51 initially scans through successive angular positions such as those indicated by arrows 55, 56 and

illustrated by the main lobe 58 of electromagnetic radiation generated by the antenna 65. In a similar manner, the direction-agile antenna 67 of the slave device 53 is directed toward the master device 51, with an antenna beam pattern illustrated by the main lobe 59 of electromagnetic radiation generated by the antenna 67.

FIG. 6 shows an embodiment of a partially cutaway perspective view of a direction-agile antenna with electronic beam scanning. In this embodiment, the antenna need not be rotated mechanically to scan the antenna beam in all directions. In the embodiment shown in FIG. 6, the electronically steered antenna comprises four antenna surfaces or planes to cover all azimuth angles, each of the antenna surfaces having a plurality of antenna elements capable of electronically steering electromagnetic signals to a selected direction in response to the direction-selection signal generated by the antenna control unit 30. In an embodiment, the antenna elements on each surface comprise an array of microstrip radiators. In an embodiment, the circuitry of the antenna control unit 30 is integrated with one of the antenna surfaces on which the arrays of microstrip radiators are disposed. In FIG. 6, for example, four antenna planes are

arranged at  $90^\circ$  to one another, with each of the antenna planes having two arrays of antenna elements, such as arrays 61 and 62.

FIGS. 7A and 7B are side-sectional views of the electronically steered direction-agile antenna of FIG. 6 obtained along sectional lines 7a-7a and 7b-7b, respectively. Power delivery lines 63 and 64 are provided to supply power to the antenna arrays such as antenna arrays 61 and 62 for transmitting electromagnetic signals.

FIG. 8 shows another embodiment of a direction-agile antenna system with electronic beam steering. Three antenna surfaces 81, 82 and 83 are implemented to cover all azimuth angles. In the embodiment shown in FIG. 8, each antenna surface has two arrays of microstrip radiator elements similar to the arrangement shown in FIGS. 6, 7A and 7B and described above. In an embodiment in which a direction-agile antenna with electronic beam steering is implemented, at least some of the antenna elements are capable of being activated or switched on while other antenna elements are switched off, to allow the mobile wireless device to adjust the RF power level of transmitted electromagnetic signals.

FIG. 9 shows a flow chart illustrating an embodiment of a method of tracking a signal in a wireless communications network by a master communications device using a direction-agile antenna system. The method generally comprises the steps of scanning an antenna beam in multiple directions, transmitting at least one polling request during the step of scanning the antenna beam, detecting a response by a source within the wireless network to the polling request, and directing the antenna beam to the source. The source which transmits a response to the polling request is a slave device that is intended to establish a wireless data link with the master device. In an embodiment in which mechanically steered direction-agile antennas are implemented, the antennas of the master and slave devices may rotate at different speeds and different angular increments which are optimized to reduce the time for establishing a wireless data link.

When the antenna of the master device is scanning over 360° in azimuth, for example, polling requests are transmitted intermittently to seek a slave device which intends to establish a wireless data link with the master device. During the scanning of the direction-agile antenna of the master device, the transceiver of the master device awaits a response by a slave device

within the network. The master device determines a desired direction of the antenna beam of the master device to the slave device by detecting a beam pattern of the RF signal carrying the response transmitted by the slave device and generating an antenna gain signal based upon the RF signal transmitted by the slave device.

In an embodiment, the RF signal received by the master device is demodulated into an IF signal which is then converted into a baseband signal. The baseband signal is processed by a baseband processor to generate an antenna gain signal, which is in turn processed by the antenna control unit to generate a motor drive signal. In an embodiment in which a mechanically steered antenna is implemented, the antenna is rotated by a motor to the desired direction in response to the motor drive signal. Once the antenna beam of the master device is directed toward the slave device, the rotation of the antenna stops. In an embodiment, the position of the antenna is memorized by the antenna control unit of the master device while the master device starts to exchange data with the slave device.

In an embodiment, fine tuning is performed by the direction-agile antenna system of the master device to maximize the gain of received RF signals as soon as the

wireless data link is established between the master device and the slave device. Fine tuning of the antenna position is accomplished by slightly changing the direction of the antenna beam and measuring the strength of received RF signals.

If the master device or the slave device is moving with respect to each other, the desired direction of the antenna beam of the master device may change over time. If the antenna control unit in the direction-agile antenna system of the master device determines that the strength of received RF signals is getting weaker, it drives the antenna to slightly different positions in an attempt to increase the strength of received RF signals. If the wireless data link is lost, the antenna beam is scanned in all directions until an RF signal from the slave device is detected to restore the wireless data link. In mobile wireless communications, the antenna beam may be scanned either continuously or in small steps in different directions to maintain the wireless data link between the master and slave devices, which may have constantly changing angular positions with respect to each other.

The method of signal tracking in a wireless network is also applicable to embodiments in which at least some of the wireless communication devices in the

network use electronically steered direction-agile  
antennas instead of mechanically steered antennas for  
wireless data links. Instead of generating motor drive  
signals to rotate the antenna, the direction of the  
5 antenna beam is switched by selectively applying RF  
power to the most properly oriented antenna elements.

In an embodiment, the direction of the antenna  
beam is changed by shifting the phases of RF signals  
transmitted by different antenna elements in a planar  
10 array using the principle of phased array radiation  
known to a person skilled in the art. Before a signal  
from the slave device is detected by the master device,  
RF power is applied to the antenna arrays on all  
surfaces of the antenna of the master device to radiate  
15 polling requests in all directions. Once a response by  
a slave device is detected, one of the antenna surfaces  
of the master device is selected to transmit RF signals  
in a selected direction at a desired power level. In a  
further embodiment, the power level of the transmitted  
20 RF signals is adjusted by activating only some of the  
antenna elements in the array while switching off other  
antenna elements.

FIG. 10 shows a flow chart of an embodiment of a  
method of tracking a signal within a wireless network  
25 by a slave device. The method generally comprises the

09709758-11000

steps of scanning the antenna beam of the slave device in multiple directions, detecting a polling request by the master device, determining a desired direction of the antenna beam to the master device, directing the antenna beam to the master device, and transmitting a response to the master device. In an embodiment, the desired direction of the antenna beam of the slave device is determined by detecting a beam pattern of an RF signal carrying the polling request by the master device and generating an antenna gain signal based upon the RF signal carrying the polling request. In an embodiment, the scanning and fine tuning of the antenna beam for the slave communication device is performed in a manner similar to that of the master device in a wireless network to establish and maintain a wireless data link.

Direction-agile antennas with electronic beam scanning typically have very fast switching times, for example, on the order of about 50 ns. These antennas can be implemented in wireless devices serving as access points in a wireless local area network (WLAN), for example. Mechanically steered antennas with a rotating speed of about 120 rotations per minute, for example, can be implemented in mobile devices with relatively small dimensions. The transmission and

reception of polling requests and responses to  
establish handshakes between master and slave  
communication devices in a wireless network may be  
performed using an industry-standard protocol according  
to IEEE 802.11, for example. Other types of protocols  
may also be used for establishing wireless data links  
between different wireless devices using direction-  
agile antenna systems within the scope of the present  
invention.

The present invention has been described with  
respect to particular embodiments thereof, and numerous  
modifications can be made which are within the scope of  
the invention as set forth in the claims.
